

Figure S4. Construction of pCX9 plasmid. The *hsp70Ab* coding sequence (excised as a *Xho*I-*Bgl*II fragment from pCX1 (Xiao et al. 2007)) was first inserted into *Xho*I-*Bgl*II-opened Sym-pUASTw (Giordano et al. 2002) to obtain pCX9.1. The mini-white sequences from Sym-pUASTw were then removed by digestion with EcoRI and self-ligation to generate pCX9. Grey arrows show the binding sites for the oligonucleotides (DJ39, DJ51) used for inverse PCR.
